

For this challenge I chose to develop a 3D prototype focused on two main features: an equipment-based inventory system and a scalable save system. Gameplay was minimal, serving mainly as a testing environment for these systems. I implemented a simple click-to-move character controller using Unity's NavMesh system. The character can move to clicked positions, pick up items from the environment, and play a death animation when health reaches zero. In this version that only happens by consuming poison items...

The save system was my main focus and the most elaborate I have implemented so far. I designed it to be generic and extendable, with a **GameSave** containing multiple "Sections" identified by GUID. Each Section maps a region of the file and is associated with an object implementing **IGameSaveSection**, which handles serialization and deserialization of its own data. I created two global Sections: one for saving loaded scenes through the Build Index and another for tracking dynamically insta...

For visuals and assets I used some Asset Store packages I already owned, combined with free Google Fonts, as well as free asset packs and resources found online. This included animated characters, textures, RPG UI icons, and small VFX. Audio was minimal since I realized sourcing and selecting suitable sounds would take too much time, so I decided not to focus on that.

The inventory features a slot-based UI with dynamic updates, drag-and-drop item movement, equipping, consuming, and tooltips showing item details on hover. For this prototype I created three items: one piece of equipment, one healing potion to restore health, and one poison to reduce health.

I used my usual context-based architecture, with **GameFlow** as the entry point and contexts for states such as main menu, new game, and loaded game. I completed the project within 48 hours, which I consider a success, especially as this was my first save system and my first slot-based inventory.
